Description

[0001] This invention relates to methods of precisely forming through holes in (100) silicon wafers by orientation dependent etching (ODE) either before or after fabrication of the integrated circuit on the wafer. More specifically, the invention involves ODE to fabricate integrated circuit (IC) wafer subunits having precision through holes which define butt edges or surfaces for forming a butted array of subunits. The ability to precisely locate and dimension butt edges or surfaces of IC wafer subunits (or chips) finds use in the precision delineation of these wafer subunits for any extended array using subunit modules. Wafer subunits are aligned in extended arrays to form, e.g., pagewidth printheads for inkjet type printers, or RIS and ROS arrays.

[0002] Previous attempts at placing through holes in silicon wafers after integrated circuit fabrication have encountered many problems. Since virtually all integrated circuit fabrication is done in (100) silicon wafers, the most precise fabrication process involves etching (111) plane through holes or recesses into a surface of the wafer. However, it was impossible to apply the standard etch resistant masking layer of pyrolytic silicon nitride over the integrated circuitry due to the high temperature (greater than 800°C) process for that film, which would cause silicon-aluminum interdiffusion. Consequently, one previous method for fabricating through holes involved etching (111) plane troughs into a back surface of a wafer opposite the upper circuit surface so that the troughs would just intersect the upper surface of the wafer. A fundamental problem with etching only through the back surface of the wafer is that the width of the opening on the unetched upper surface is a function of the wafer thickness. Since it is not uncommon for wafers to have variations in thickness, it has not been possible to precisely locate openings on the circuit side of the wafer. For example, if the etch mask is designed to produce a through hole H adjacent the integrated circuit IC and just reaching the upper integrated circuit surface CS of a 508 μm thick wafer W_1 (see Fig. 1B), it will actually produce a 35.6 μm wide opening on a 483 μm thick wafer W_2 (Fig. 1A) and will not produce any opening at all on a 533 μm thick wafer W_3 (Fig. 1C).

[0003] The effect of variations in wafer thickness is addressed in US-A-4,169,008 to Kurth. Kurth discloses a method of forming an ink jet nozzle in a (100) silicon wafer by etching through obverse and reverse surfaces of the wafer. The method does not produce butt edges and is not performed after integration circuit fabrication on the wafer. The etch resistant layer used by Kurth'008 is not plasma silicon nitride.

[0004] Thermal ink jet printers contain printheads, such as roofshooter printheads shown in Figure 2 and described in US-A-4,789,425 to Drake et al. The printheads are constructed from silicon wafer subunits (or chips) 1 which include nozzles 2, reservoirs 3 for conducting ink to the nozzle outlets and integrated circuitry

4. The integrated circuitry includes a resistive heater element which responds to an electrical impulse to vaporize a portion of the ink in a passageway 6 which provides the motive force to form an ink drop which is expelled onto a recording medium. Some printheads, such as sideshooter printheads shown in Figure 3 and described in US-A-4,601,777 to Hawkins et al, are formed from a number of wafer subunits S_1, S_2, S_3 butted together and layered upon a support substrate. The sideshooter printhead includes nozzles 7 and resistive heater element circuit 8 located on a heater substrate 9 for controlling ink output from each nozzle 7. In each case, the printhead is wired to a daughter board, placed in communication with a source of ink and mounted on a carriage of an ink jet printer for reciprocation across the surface of a recording medium, such as paper. Alternatively, a pagewidth array of wafer subunits, as shown in Figure 4, can be formed by butting together a plurality of subunits S_1, S_2, S_3 into the length of a pagewidth. In a pagewidth array configuration, the array is fixed and the recording medium moves at a constant velocity in a direction perpendicular to the array.

[0005] Since silicon wafers are not currently available having a length corresponding to a pagewidth, the current practice is to form the nozzles, passageways and integrated circuitry on silicon wafers, separate these wafers into wafer subunits (or chips) which contain butt surfaces or edges, align these subunits along their butt surfaces or edges into an array having a length of a pagewidth, and attach the array to a substrate to form a pagewidth printhead. The layering of the wafers, if necessary, to form the complete printhead can be performed before or after separation into subunits. Since many wafer subunits are aligned to form an array, each subunit must be uniform. In order for the subunits to be uniform, the location of the butt edges or surfaces relative to the circuitry must be precise. Additionally, since the step of separating a wafer into subunits is performed as a batch, well prior to the step of aligning the subunits into arrays, the later step usually involves selecting subunits from a bin which contains subunits having a variety of thicknesses. When the subunits S_1, S_2 are formed with diagonal butt surfaces, a difference in height Δh between adjacent subunits results in a lateral shift $0.7\Delta h$ of the circuit surfaces CS of these subunits (see Figure 5).

[0006] One previous technique for forming butt edges, shown in Figures 6A-6B, involves orientation dependent etching a groove 10 on one surface of the wafer, placing a dice cut 11 in the opposite surface of the wafer and applying a force F to fracture break the wafer along line 12 into subunits to produce butt edges 13. Adjacent subunits are then butted together at the butt edges 13 (Fig. 6B). Disadvantages of this technique are: the fracture edges can produce cracked passivation up to 50 micrometers away, the butt edges 13 are razor edges which are easily damaged, and any difference in chip thickness Δh between two subunits results in a lat-

eral shift of $0.7\Delta h$ of one chip surface relative to the other. The lateral shift is due to the angle of the (111) etched surfaces.

[0007] Another previous method for forming butt surfaces, illustrated in Figure 3, involves orientation dependent etching troughs entirely through the wafer, giving a parallelogram cross section to the wafer. By this method, the butt surfaces 15, 16 are crystal (111) planes. Advantages of this method are (1) the butt surfaces are formed gently by wet etching, and (2) the butt surface is a robust crystal plane. A disadvantage is that two separate through etches are required and the area between the butted surfaces is so large that dirt particles can prevent intimate butting.

[0008] Another previous method, illustrated in Figures 7A and 7B, which requires only one through etch, involves making at least one through etch 20 on one surface of the wafer to define a first butt edge 21 and dividing the wafer into DIE 1 and DIE 2, forming a trough 22 on the other surface of the wafer, and then making a dice cut 23 through the trough 22 to form a second butt edge 24. The first butt edge 21 of each subunit is butted against the second butt edge 24 of an adjacent subunit (Fig. 7B) to form the array. This method reduces the amount of etch time required and also reduces the butt edge area. However, since a dice cut is required, it is possible to produce cracked passivation. This method also is susceptible to a lateral displacement of $0.7\Delta h$ due to differences in adjacent chip height Δh .

[0009] A further previous method, illustrated in Figures 8A and 8B, involves producing butt edges by reactive ion etching (RIE) from the circuit surface to a groove G cut into the base surface. This method is advantageous in that it produces vertical butt surfaces 25, 26 and thus differences in the height of adjacent butting chips do not result in lateral displacements. A disadvantage is that the RIE trenches must be etched prior to metal oxide silicon (MOS) fabrication due to potential oxide damage from the high energy ions. Reference is made to US-A-4 822 755.

[0010] US-A-4,601,777 to Hawkins et al discloses thermal ink jet printheads which are formed in (100) silicon wafers. The wafers can be separated into subunits to form printheads and the printheads can be aligned into pagewidth arrays. The wafers are separated into printheads by dicing.

[0011] US-A-4,612,554 to Poleshuk discloses a thermal ink jet printhead and method of making same. The printheads are formed from (100) silicon wafers on which the integrated circuits are fabricated after application of an etch resistant pyrolytic silicon nitride layer. Poleshuk discloses dicing to form butt edges.

[0012] US-A-4,784,721 to Holmen et al discloses a process for fabricating a thin film microsensor for airflow. The process only etches through a back surface of a (100) silicon wafer, does not provide a through hole in the wafer and does not discuss the fabrication of butt edges.

[0013] T.S. Kuan et al. in IBM Technical Disclosure Bulletin Vol. 21, No. 6, November 1978, pp.2585-2586 discloses a two sided groove etching method to produce silicon ink jet nozzles. The method involves (pyrocatechol) etching a groove defined by (111) surfaces in opposing surfaces of a (100) Si wafer, the etching commencing at points directly opposite each other so that the grooves eventually join up in the middle of the wafer.

[0014] It is an object of the present invention to form precision through holes in (100) silicon wafers using orientation dependent etching, particularly after fabrication of the integrated circuit on the wafer.

[0015] It is another object of the present invention to fabricate (100) silicon wafer subunits having precision butt edges.

[0016] Another object of the present invention is to fabricate pagewidth printheads by precisely aligning adjacent (100) silicon wafer subunits.

[0017] According to one aspect of the invention, there is provided a method of separating one or more subunits from a silicon wafer having a (100) crystallographic orientation, the method comprising: anisotropically etching the wafer by orientation dependent etching through at least one pair of etch openings corresponding to the boundaries of the subunits and being formed in etch resistant layers on the upper and lower face of the wafer, respectively, wherein the or each etch opening in the etch resistant layer on lower face is substantially vertically aligned within a predetermined tolerance with a respective space etch opening in the etch resistant layer on the upper face, thereby forming at least one pair of parallel, aligned recesses at the etch openings, the recesses being bounded by surfaces lying in planes having a (111) crystallographic orientation, the width of the etch openings of each pair being such that the etched recesses each have a depth less than the thickness of the wafer but each pair of parallel, aligned recesses intersects within the thickness of the wafer to form an opening through the wafer.

[0018] The invention further provides a method of mounting subunits in a linear array, according to claims 7, 8 and 9 of the appended claims.

[0019] The invention further comprises a method of fabricating a printhead for an ink jet printing apparatus, according to claim 10 of the appended claims.

[0020] The present invention preferably makes use of an etchant material, e.g., plasma silicon nitride, which can be applied at a relatively low temperature between 250°C and 450°C , which enables masking of the IC side of the wafer without silicon-aluminum interdiffusion.

[0021] In one application of the present invention, an integrated circuit is fabricated on a (100) silicon wafer. After fabrication of the IC, an etch resistant layer is applied on circuit and base surfaces of the wafer. These etch resistant layers are patterned to form upper and lower etch openings and the wafer is anisotropically etched to form upper and lower recesses which correspond to the upper and lower etch openings. These up-

per and lower recesses intersect one another to form a through opening which is precisely aligned with the integrated circuitry on the wafer.

[0022] The wafer can then be separated along the through holes to form wafer subunits (or chips) which have precisely defined butt edges. These butt edges are formed without dicing thereby reducing the risk of damage to the passivation layer of the wafer. The wafer subunits can be aligned in an array to form a pagewidth ink jet printhead or any other type device requiring an extended array of (100) silicon wafer subunits.

[0023] The invention will be described in detail with reference to the following illustrations in which:

Figures 1A-1C show a prior art method of forming butt edges by anisotropically etching only through a base surface of a wafer;
Figure 2 shows one type of ink jet printhead;
Figure 3 shows an array of ink jet printheads;
Figure 4 shows another array of ink jet printheads;
Figure 5 shows wafer subunits having different thicknesses butted against one another;

Figures 7A and 7B show a prior art method of forming butt edges by anisotropic etching and dicing;
Figures 8A and 8B show a prior art method of forming butt edges by reactive ion etching;
Figures 9A-9F show an embodiment of the present invention;
Figures 10A-10D show a second embodiment of the present invention where contact pad vias are formed;
Figures 11A and 11B show yet another embodiment of the present invention; and
Figures 12A and 12B show a further embodiment of the present invention.

[0024] The present invention involves fabricating a through opening of predetermined dimensions in a (100) silicon wafer by orientation dependent etching after the fabrication of integrated circuits on the wafer. The opening extends through the wafer between the circuit surface of the wafer and the parallel base surface of the wafer. By this method, the through opening can be precisely located relative to the integrated circuit on the circuit surface of the wafer. Butt edges or surfaces can then be formed along the through openings so that the butt edges or surfaces have the precise location and dimensions of the through opening.

[0025] As illustrated in Figure 9A, a (100) wafer 30, preferably of silicon, is supplied having an upper surface 31 (hereafter referred to as the circuit surface) and an opposite base surface 32. The (100) wafer includes a (100) plane defined in terms of mono-crystalline silicon electro-physical geometry as a plane parallel to surfaces of the parallel-piped structure of the crystal. The upper and base surfaces are generally within $\pm 1^\circ$ of this

(100) plane. Another plane of crystalline silicon, generally diagonally of the (100) plane, and known to the artisan as the (111) plane, lies at an angle, for silicon, of 54.7° to the (100) plane. The present invention makes use of the selection of an etchant which etches through the (100) planes much faster than the (111) planes.

[0026] A (100) silicon wafer 30 having circuit and base surfaces 31 and 32, respectively, is obtained and the integrated circuitry 33 is fabricated on the circuit surface of the wafer. An etch resistant layer 34 (Fig. 9B) of plasma silicon nitride is formed on the circuit and base surfaces of the wafer. The etch resistant plasma silicon nitride layer on the circuit surface is patterned to produce an upper etch opening 35 (Fig. 9C) having a precise location and precise dimensions which define the predetermined location and dimensions of the through opening. The plasma silicon nitride layer on the base surface is patterned to produce a lower etch opening 36 which is aligned with the upper etch opening 35 within a predetermined tolerance. The wafer is then anisotropically etched to produce a first recess 37 (Fig. 9D) corresponding to the upper etch opening 35 in the circuit surface of the wafer and a second recess 38 corresponding to the lower etch opening in the base surface of the wafer. The first recess 37 terminates at point P, but the second recess 39 continues to etch toward the first recess 37 as illustrated by the arrows in the second recess. Each of these first and second recesses are bounded by (111) plane sidewalls. The anisotropic etching of the second recess 38 eventually intersects the first recess 37 (Fig. 9E) to form a through opening 39 bounded by (111) plane sidewalls 40, 41 (Fig. 9F). This through opening has its dimensions and location defined by the patterning of the upper etch opening on the circuit surface of the wafer.

[0027] During etching, the (111) planes of the first recess 37 are rapidly etched and exchanged for the (111) planes parallel to those of the second recess 38 because, at the external intersection I of the (111) planes of the first and second recesses (Fig. 9E), etching occurs rapidly relative to the etch rate perpendicular to the (111) planes. However, while the original (111) planes of the first recess 37 are rapidly etched away, a new set of (111) planes emerge, which are also determined by the pattern for the upper etch opening 35. This creates an etch ledge 42 which moves toward and finally terminates at the pattern for the lower etch opening 36. Two internally intersecting (111) planes intersect at the etch ledge 42 and terminate the etching.

[0028] As noted above, the invention employs etch patterns on opposite sides of the wafer. The pattern for the lower etch opening 36 is to etch through the wafer while the pattern for the upper etch opening 35 (which is usually smaller than the pattern for the lower etch opening) is designed to control the placement and dimensions of the entire through opening.

[0029] The present invention makes use of an etch resistant material which is applied at a temperature in

the range of 250°C to 450°C. This enables the etch resistant layer to be applied over the integrated circuit without causing silicon-aluminum interdiffusion, which would occur if a high temperature (800°C) pyrolytic silicon nitride etch resistant material were applied. Although plasma silicon nitride is preferred etch resistant material, other materials can be used so long as they can be applied at a temperature in the range of 250°C to 450°C, preferably about 350°C.

[0030] By this method, the location and dimensions of a through opening are controlled by the etch opening formed in the circuit surface of the wafer regardless of the thickness of the wafer between the circuit and base surfaces. This is one important advantage since previous methods were prone to errors in through opening location due to variations in wafer thickness.

[0031] One method of applying the etch resistant layer to both the circuit and base surfaces makes use of a graphite boat. The etch resistant layer is first applied to one of the surfaces, e.g., the circuit surface, to form a first coated surface. The first coated surface is then placed on a graphite boat and the etch resistant layer is applied to the other surface. Either surface can be coated first. Alternative methods of coating the wafer can be employed so long as both the circuit and base surfaces are sufficiently coated with the etch resistant layer.

[0032] The step of patterning the etch resistant layer to form the upper and lower etch openings can be done using a double sided aligner, although alternative methods can also be used. The etch pattern on the circuit side of the wafer serves to define the precise opening of the ODE through hole, as well as precisely define its location. The etch pattern on the back side of the wafer is usually larger and serves to provide most of the through etch. Consequently, the lower etch opening need not be located as precisely as the upper etch opening. However, the lower etch opening must be aligned with the upper etch opening within a predetermined tolerance so that the recess formed during anisotropic etching intersects the recess which corresponds to the upper etch opening in the circuit surface.

[0033] In one preferred embodiment of the present invention, illustrated in Figures 10A-10D, the wafer 50 is fabricated to provide for opening the contact pad 51 of the integrated circuit wafer after the anisotropic etch is completed. This embodiment, the etch resistant layer 52 applied to the circuit surface 53 is patterned to produce a contact pad opening 54 at a predetermined location on the integrated circuit IC (Fig 10A). A low temperature oxide layer 55 is applied over the circuit surface to expose the upper etch opening 35 but cover the contact pad opening 54 (Fig 10B). This low temperature oxide layer can be applied by chemical vapor deposition (CVD). An additional etch resistant layer 56 is applied over the low temperature oxide layer 55 and is also patterned to expose the upper etch opening 35 and cover the contact pad opening 54 (Fig 10C). After the wafer is anisotropically etched, the additional etch resistant layer

56 is removed, exposing the low temperature oxide layer 55, which is subsequently removed to expose the original etch resistant layer 52 having the contact pad opening (Fig 10D). This permits the contact pad to be wire banded. The additional etch resistant layer 56 can be removed by, e.g., a CF_4/O_2 plasma or hot phosphoric acid. The low temperature oxide is easily removed in, e.g., a buffered HF solution.

[0034] Since the method of the present invention enables through etched holes to be precisely defined (both dimensionally and positionally) by standard photolithography on the integrated circuit side of the wafer, it finds use in a number of applications. The method can be used to produce butt edges on chips without any mechanical steps, which is beneficial in that it reduces the number of work stations required and prevents passivation layer damage.

[0035] Another embodiment of the present invention, illustrated in Figures 11A and 11B, controls the anisotropic etching of the first and second recesses 65, 66 so that the etching stops at first and second predetermined depths between the circuit and base surfaces of the wafer. This method finds particular application in fabricating wafer subunits having buttable edges located at a uniform distance below the circuit surface of the wafer.

[0036] One method for producing a buttable edge in a (100) silicon wafer with the buttable edge located between a circuit surface of the wafer and an opposite parallel base surface of the wafer involves controlling the etching of the lower base surface of the wafer to stop at a depth less than the thickness of the wafer. A (100) silicon wafer 60 (Fig. 11A) is obtained and the integrated circuits 67 are fabricated on the circuit surface of the wafer. An etch resistant layer 62, 63 is applied onto the circuit and base surfaces of the wafer in a manner similar to the described above. As stated earlier, the etch resistant layer should be applied at a temperature between 250°C and 450°C, and is preferably plasma silicon nitride, if the etch resistant layer is to be applied after the integrated circuits have been fabricated on the circuit surface of the wafer. Next, the etch resistant layer on the base surface is patterned to produce a lower etch opening. The wafer is anisotropically etched to produce a recess 66 (Fig 11A) corresponding to the lower etch opening in the base surface of the wafer and bounded by (111) plane sidewalls. This recess 66 has a first predetermined depth less than the thickness of the wafer. Another etch resistant layer 64 is reapplied onto the base surface to prevent further etching of the recess 66. The circuit surface of the wafer is then patterned with an etch resistant material to produce an upper etch opening having a predetermined location in alignment with the recess 66 and predetermined dimensions with respect to the integrated circuits. The wafer is anisotropically etched to produce a trough 65 corresponding to the upper etch opening in the circuit surface and bounded by (111) plane sidewalls. The anisotropic etching of the trough 65 continues to a second predetermined

depth so as to intersect the recess and form the buttable edge E defined by the intersection of the (111) plane sidewalls of the recess 66 and trough 65. Adjacent subunits S_1 , S_2 , S_3 are then butted together along their buttable edges E (Fig 11B).

[0037] One way to control the depth of etching is to implant or diffuse a relatively shallow (e.g., 2 micrometer) p + region 61 into the silicon wafer prior to circuit fabrication. After completion of the IC's, application and patterning of the etch resistant layers is performed. An etchant which is dopant sensitive such as, e.g., KOH is chosen so that etching is considerably slowed when the p + region is reached, thus ensuring that a thin (e.g., 2 micrometer) reproducible silicon layer will remain. Thus, provided that the p + region is able to sufficiently slow the etch, the depth of the etch from the base surface can be controlled to stop at a depth less than the thickness of the wafer and a uniform distance from the circuit surface of the wafer.

[0038] Thus, an anisotropic etching of the wafer to form the trough of predetermined depth in the circuit surface defines the location of the buttable edge by controlling the intersection of the (111) plane sidewalls of the recess and trough. Additionally, the location, size and alignment of the etch openings on the base surface are not critical since the point of intersection of the upper trough and lower recess is controlled by the depth of the lower recess and size of the upper trough. This method is useful for, e.g., producing printhead wafer subunits which are then aligned in series with their butting edges adjacent to and butting against one another in a length corresponding to a page width. This series of aligned wafer subunits is then secured to a support substrate having a length corresponding to a pagewidth. Since the butt edges are small, the possibility of dirt contaminating the butting surfaces is reduced.

[0039] As illustrated in Figures 12A and 12B, a further method for producing a buttable surface in a silicon (100) wafer by orientation dependent etching after processing of integrated circuits on the wafer involves etching the circuit surface first. An alignment hole 71 is formed at a periphery of a (100) silicon wafer 70 by orientation dependent etching, the alignment hole defining a (111) plane surface 72. Integrated circuits 73 are fabricated on the circuit surface in alignment with the (111) surface 72 of the alignment hole 71. An etch resistant layer 74, 75 (e.g., plasma silicon nitride) is applied on the circuit and base surfaces of the wafer. The etch resistant layer on the circuit surface is patterned to produce an upper etch opening which is then anisotropically etched to produce a trough 76 corresponding to the upper etch opening and bounded by (111) plane sidewalls, the trough having a first predetermined depth and defining a first buttable (111) surface 80. The anisotropic etching is stopped and an etch resistant layer 77 is re-applied on the circuit surface to prevent further etching of the trough 76. The etch resistant layer on the base surface is patterned to produce two spaced lower etch

openings 81, 81, each opening being located on the base surface at a predetermined location with respect to the alignment hole 71. A first one 81 of the openings is aligned with the trough 76. The wafer is anisotropically etched to produce two recesses 78, 79 each corresponding to one of the lower etch openings and bounded by (111) plane sidewalls. A first lower recess 78, corresponding to the first one 81 of the lower etch openings, has a second predetermined depth sufficient to intersect the trough 76. The other recess 79 is permitted to anisotropically etch through the wafer to define a second buttable surface 90 parallel to a (111) plane surface 72 of the alignment hole. Upon separation, the subunits are butted with the first buttable surface 80 of one subunit contacting the second buttable surface 90 of an adjacent subunit. This method produces subunits with precise, rebuts butting edges with no mechanical or ion beam damage.

[0040] While the present invention has been described with reference to forming through openings those skilled in the art recognize that the through opening may define buttable surfaces for butting adjacent subunits together in a precisely aligned array. For example, multiple subunits may be formed from a single wafer by ODE of the wafer in accordance with the present invention and dividing the wafer into the subunits along the buttable surfaces formed by the ODE.

[0041] Further, the present invention has been described by formation of through holes after formation of integrated circuitry on the wafer. However, the invention is applicable equally to manufacture of wafers prior to integrated circuit fabrication, for example by providing a method of cutting wafers into subunits without dicing.

[0042] The invention has been described with reference to the preferred embodiments thereof which are intended to be illustrative rather than limiting.

Claims

1. A method of separating one or more subunits from a silicon wafer (30) having a (100) crystallographic orientation, the method comprising:
anisotropically etching the wafer by orientation dependent etching through at least one pair of etch openings (35,36) corresponding to the boundaries of the subunits and being formed in etch resistant layers (34) on the upper (31) and lower face (32) of the wafer, respectively, wherein the or each etch opening (36) in the etch resistant layer on the lower face is substantially vertically aligned within a predetermined tolerance with a respective space etch opening (35) in the etch resistant layer on the upper face, thereby forming at least one pair of parallel, aligned recesses (37,38) at the etch openings, the recesses being bounded by surfaces lying in planes having a (111) crystallographic orientation, the width of the etch openings of each pair being

such that the etched recesses each have a depth less than the thickness of the wafer but each pair of parallel, aligned recesses (37,38) intersects within the thickness of the wafer to form an opening through the wafer.

2. The method of claim 1 wherein the orientation dependent etch of the recess formed at the lower etch opening (36) continues until the opening through the wafer is bounded by surfaces lying in (111) crystallographically oriented planes extending from the edges of the etch opening (35) at the upper face (31) of the wafer toward the lower face (32) of the wafer and forming an acute angle with the upper face of the wafer.
3. The method of any one of claims 1 and 2 wherein the recess (37) in the upper face and the recess (38) in the lower face are etched at the same time.
4. The method of claim 1 further comprising applying the etch resistant layers (62,63) to the wafer (60) with the etch opening of said at least one pair only in the etch resistant layer (63) on the lower face of the wafer and etching the wafer to form the recess (66) in the lower face, wherein the anisotropic etching of the recess in the lower face of the wafer is controlled, preferably to means of a doped layer of uniform depth adjacent the upper face, to stop the etching of the lower recess at a first predetermined depth, then re-applying an etch resistant layer (64) so as to cover the recess (66) in the lower face and forming the etch opening of said at least one pair in the etch resistant layer (62) on the upper face of the wafer, and then etching the wafer to form the recess (65) in the upper face, wherein the etching of the recess (65) is controlled to stop at a second predetermined depth by the re-applied etch resistant layer (64), the opening through the wafer being formed by the intersection of the upper recess with the lower recess.
5. The method of claim 1 further comprising applying the etch resistant layer (74) to the wafer with the etch opening of said at least one pair only on the upper face of the wafer and etching the wafer to form the recess in the upper face, thereby forming a first butt surface (80) in a (111) crystallographically oriented plane, then re-applying an etch resistant layer (77) so as to cover the recess (76) in the upper face and forming the etch opening (81) of the at least one pair and a further etch opening (81) at the opposite boundary of each subunit in the etch resistant layer (75) on the lower face on either side of each subunit, and etching the wafer to form respective recesses (78,79) in the lower face, thereby forming a second butt surface (90) at the further etch opening (81).

6. The method of any one of claims 1 to 5 wherein integrated circuitry is fabricated on the upper face of the wafer prior to application of the etch resistant layers.
7. A method of mounting a plurality of subunits in a linear array, comprising the method of claim 2 or 3, and further comprising placing a butt edge (91, 92) defined by the intersection of the upper face of the subunit and the surface of the subunit formed by etching the lower recess in contact with a corresponding butt edge of an adjacent subunit.
8. A method of mounting a plurality of subunits in a linear array, comprising the method of claim 4, and further comprising placing a butt edge (93) defined by the intersection of a surface of the subunit formed by etching the upper recess with a surface of the subunit formed by etching the lower recess in contact with a corresponding butt edge of an adjacent space subunit, wherein the butt edge (93) is located at a distance corresponding to the second predetermined depth from the upper face.
9. A method of mounting a plurality of subunits in a linear array, comprising the method of claim 5, further comprising, for the or each subunit, placing the first butt surface (80) of the subunit in contact with the second butt surface (90) of an adjacent subunit.
10. A method of fabricating a printhead for an ink jet printing apparatus, comprising the method of any of claims 7 to 9, wherein the subunits comprise ink jet printing devices.

Patentansprüche

1. Verfahren zum Trennen von einer oder mehreren Teileinheiten von einem Siliziumwafer (30) mit einer (100)-kristallographischen Ausrichtung, wobei das Verfahren umfaßt:
anisotropisches Ätzen des Wafers mit Hilfe eines von der Ausrichtung abhängigen Ätzens durch wenigstens ein Paar von Ätzöffnungen (35, 36), die den Grenzen der zu bildenden Teileinheiten entsprechen und in ätzbeständigen Schichten (34) jeweils auf der oberen Fläche (31) und der unteren Fläche (32) des Wafers ausgebildet sind, wobei die oder jede Ätzöffnung (36) in der ätzbeständigen Schicht auf der unteren Fläche im wesentlichen vertikal innerhalb einer vorbestimmten Toleranz mit einer räumlich entsprechenden Ätzöffnung (35) in der ätzbeständigen Schicht auf der oberen Fläche ausgerichtet ist, um wenigstens ein Paar von parallelen, miteinander ausgerichteten Vertiefungen (37, 38) an den Ätzöffnungen zu bilden, wobei die Ver-

- tiefungen durch Oberflächen begrenzt sind, die in Ebenen mit einer (111)-kristallographischen Ausrichtung liegen, wobei die Ätzöffnungen jedes Paares eine derartige Breite aufweisen, daß die geätzten Vertiefungen eine Tiefe aufweisen, die geringer ist als die Dicke des Wafers, wobei sich aber jedes Paar aus ausgerichteten Vertiefungen innerhalb der Dicke des Wafers überschneidet, um eine Öffnung durch den Wafer zu bilden.
2. Verfahren nach Anspruch 1, wobei das von der Ausrichtung abhängige Ätzen der an der unteren Ätzöffnung (36) gebildeten Vertiefung fortfährt, bis die Öffnung durch den Wafer durch Oberflächen begrenzt ist, die in (111)-kristallographisch ausgerichteten Ebenen liegen, die sich von den Kanten der Ätzöffnung (35) an der oberen Fläche (31) des Wafers zu der unteren Fläche (32) des Wafers erstrecken und einen spitzen Winkel mit der oberen Fläche des Wafers bilden.
 3. Verfahren nach Anspruch 1 oder 2, wobei die Vertiefung (37) in der oberen Fläche und die Vertiefung in der unteren Fläche (33) gleichzeitig geätzt werden.
 4. Verfahren nach Anspruch 1, das weiterhin umfaßt: das Aufbringen von ätzbeständigen Schichten (62, 63) auf dem Wafer (60), wobei die Ätzöffnung des wenigstens einen Paares in der ätzbeständigen Schicht (63) auf der unteren Fläche des Wafers ausgebildet ist, und das Ätzen des Wafers, um die Vertiefung (66) in der unteren Fläche zu bilden, wobei das anisotropische Ätzen der Vertiefung in der unteren Fläche vorzugsweise durch eine dotierte Schicht mit gleichmäßiger Breite in Nachbarschaft zu der oberen Fläche kontrolliert wird, um das Ätzen der unteren Vertiefung bei einer ersten vorbestimmten Tiefe zu stoppen, dann das erneute Auftragen einer ätzbeständigen Schicht (64), um die Vertiefung (66) in der unteren Fläche zu bedecken, und das Bilden der Ätzöffnung des wenigstens einen Paares in der ätzbeständigen Schicht (62) auf der oberen Fläche des Wafers, dann das Ätzen des Wafers, um die Vertiefung (65) in der oberen Fläche zu bilden, wobei das Ätzen der Vertiefung (65) durch die erneut aufgetragene ätzbeständige Schicht (64) kontrolliert wird, um bei einer zweiten vorbestimmten Tiefe zu stoppen, wobei die Öffnung durch den Wafer durch die Überschneidung der oberen Vertiefung mit der unteren Vertiefung gebildet wird.
 5. Verfahren nach Anspruch 1, das weiterhin umfaßt: Aufbringen der ätzbeständigen Schicht (74) auf dem Wafer, wobei die Ätzöffnung des wenigstens einen Paares nur auf der oberen Fläche des Wafers ausgebildet ist, und Ätzen des Wafers, um die Vertiefung in der oberen Fläche zu bilden, wodurch eine erste Stoßfläche (80) in einer (111)-kristallographisch ausgerichteten Ebene gebildet wird, dann erneutes Aufbringen einer ätzbeständigen Schicht (77), um die Vertiefung in der oberen Fläche zu bedecken, und Bilden der Ätzöffnung (81) des wenigstens einen Paares und einer weiteren Ätzöffnung (81) an der entgegengesetzten Grenze jeder Teileinheit in der ätzbeständigen Schicht (75) in der unteren Fläche auf beiden Seiten jeder Teileinheit, dann Ätzen des Wafers, um entsprechende Vertiefungen (78, 79) in der unteren Fläche zu bilden, wodurch eine zweite Stoßfläche (90) an der weiteren Ätzöffnung (81) gebildet wird.
 6. Verfahren nach wenigstens einem der Ansprüche 1 bis 5, wobei die integrierte Schaltung auf der oberen Fläche des Wafers vor dem Aufbringen der ätzbeständigen Schichten hergestellt wird.
 7. Verfahren zum Anbringen einer Vielzahl von Teileinheiten in einer linearen Anordnung, das das Verfahren von Anspruch 2 oder 3 und weiterhin das Platzieren einer Stoßfläche (91, 92), die durch die Überschneidung der oberen Fläche der Teileinheit mit der durch das Ätzen der unteren Vertiefung ausgebildeten Oberfläche gebildet wird, in Kontakt mit einer entsprechenden Stoßfläche einer benachbarten Teileinheit umfaßt.
 8. Verfahren zum Anbringen einer Vielzahl von Teileinheiten in einer linearen Anordnung, das das Verfahren von Anspruch 4 und weiterhin das Platzieren einer Stoßfläche, die durch die Überschneidung einer durch das Ätzen der oberen Vertiefung gebildeten Oberfläche der Teileinheit mit einer durch das Ätzen der unteren Vertiefung gebildeten Oberfläche der Teileinheit definiert wird, in Kontakt mit einer entsprechenden Stoßfläche einer räumlich benachbarten Teileinheit umfaßt, wobei die Stoßfläche (93) mit einem Abstand zu der oberen Fläche angeordnet ist, der der zweiten vorbestimmten Tiefe entspricht.
 9. Verfahren zum Befestigen einer Vielzahl von Teileinheiten in einer linearen Anordnung, das das Verfahren von Anspruch 5 und weiterhin für jede Teileinheit das Platzieren der ersten Stoßfläche (80) der Teileinheit in Kontakt mit der zweiten Stoßfläche (90) einer benachbarten Teileinheit umfaßt.
 10. Verfahren zum Herstellen eines Druckkopfes für eine Tintenstrahl Druckvorrichtung, die das Verfahren nach wenigstens einem der Ansprüche 7 bis 9 umfaßt, wobei die Teileinheiten Tintenstrahl Druckeinrichtungen umfassen.

Revendications

1. Procédé de séparation d'un ou plusieurs modules d'une plaquette (30) de silicium d'orientation cristallographique (100), le procédé comprenant :
 - l'attaque anisotrope de la plaquette par une attaque dépendant de l'orientation au travers d'au moins une paire d'ouvertures (35, 36) d'attaque correspondant aux frontières des modules et étant respectivement formées dans des couches (34) résistantes à l'attaque sur la face supérieure (31) et inférieure (32) de la plaquette, l'ouverture, ou chaque ouverture (36) d'attaque pratiquée dans la couche résistante à l'attaque sur la face inférieure étant alignée sensiblement verticalement, à une tolérance prédéterminée près avec une ouverture (35) d'attaque respective pratiquée dans la couche résistante à l'attaque sur la face supérieure, en formant ainsi au moins une paire d'évidements (37, 38) alignés parallèles au niveau des ouvertures d'attaque, les évidements étant délimités par des surfaces se situant dans des plans d'orientation cristallographique (111), la largeur des ouvertures d'attaque de chaque paire étant telle que les évidements attaqués aient chacun une profondeur inférieure à l'épaisseur de la plaquette mais que chaque paire d'évidements (37, 38), des évidements (37, 38) alignés forment une intersection avec l'épaisseur de la plaquette en formant une ouverture à travers la plaquette.
2. Procédé selon la revendication 1, dans lequel l'attaque dépendant de l'orientation de l'évidement formé au niveau de l'ouverture (36) d'attaque inférieure se poursuit jusqu'à ce que l'ouverture traversant la plaquette soit délimitée par des surfaces se situant dans des plans d'orientation cristallographique (111) s'étendant depuis les bords de l'ouverture (35) d'attaque au niveau de la surface (31) supérieure de la plaquette jusqu'à la face (32) inférieure de la plaquette et formant un angle aigu avec la surface supérieure de la plaquette.
3. Procédé selon l'une quelconque des revendications 1 et 2, dans lequel l'évidement (37) pratiqué dans la face supérieure et l'évidement (38) pratiqué dans la face inférieure sont attaqués en même temps.
4. Procédé selon la revendication 1, comprenant en outre l'application des couches (62, 63) résistantes à l'attaque (60) de telle façon que l'ouverture de ladite au moins une paire ne soit formée que dans la couche (63) résistante à l'attaque se trouvant sur la face inférieure de la plaquette, et l'attaque de la plaquette pour former l'évidement (66) dans la face inférieure, dans lequel l'attaque anisotrope de l'évidement pratiqué dans la face inférieure de la plaquette est régulée, de préférence au moyen d'une couche dopée de profondeur uniforme adjacente à la face supérieure, pour arrêter l'attaque de l'évidement inférieur à une première profondeur prédéterminée, puis l'application à nouveau d'une couche (64) résistante à l'attaque de façon à recouvrir l'évidement (66) pratiqué dans la face inférieure et la formation de l'ouverture d'attaque de ladite au moins une paire dans la couche (62) résistante à l'attaque sur la face supérieure de la plaquette, et ensuite, l'attaque de la plaquette pour former l'évidement (65) dans la face supérieure, l'attaque de l'évidement (65) étant régulée pour s'arrêter à une seconde profondeur prédéterminée du fait de la nouvelle application de la couche (64) résistante à l'attaque, l'ouverture à travers la plaquette étant formée par l'intersection entre l'évidement supérieur et l'évidement inférieur.
5. Procédé selon la revendication 1, comprenant en outre l'application de la couche (74) résistante à l'attaque à la plaquette, de telle façon que l'ouverture d'attaque de ladite au moins une paire ne soit formée que sur la face supérieure de la plaquette, et l'attaque de la plaquette pour former l'évidement dans la face supérieure, en formant ainsi une première surface (80) de butée dans un plan d'orientation cristallographique (111), puis l'application de nouveau d'une couche (77) résistante à l'attaque de façon à couvrir l'évidement (76) pratiqué dans la face supérieure, et la formation de l'ouverture (81) d'attaque de ladite au moins une paire et d'une ouverture (81) d'attaque supplémentaire sur la frontière opposée de chaque module dans la couche (75) résistante à l'attaque sur la face inférieure de l'une ou l'autre des faces de chaque module, et l'attaque de la plaquette de façon à former des évidements (78, 79) respectifs dans la face inférieure, en formant ainsi une seconde surface (90) de butée au niveau de l'ouverture (81) d'attaque supplémentaire.
6. Procédé selon l'une quelconque des revendications 1 à 5, dans lequel le circuit intégré est fabriqué sur la face supérieure de la plaquette avant l'application des couches résistantes à l'attaque.
7. Procédé de montage d'une pluralité de modules dans un groupement linéaire, comprenant le procédé selon la revendication 2 ou 3, et comprenant en outre la mise en place d'un rebord (91, 92) de butée défini par l'intersection entre la face supérieure du module et la surface du module formé par attaque de l'évidement inférieur en contact avec le bord de butée correspondant d'un module adjacent.
8. Procédé de montage d'une pluralité de modules dans un groupement linéaire, comprenant le procé-

dé selon la revendication 4, et comprenant en outre la mise en place d'un bord (93) de butée défini par l'intersection entre une surface du module formé par attaque de l'évidement supérieur et une surface du module formé par attaque de l'évidement inférieur en contact avec un bord de butée correspondant d'un module adjacent, le bord (93) de butée étant situé à une distance correspondant à la seconde profondeur prédéterminée par rapport à la face supérieure.

9. Procédé de montage d'une pluralité de modules dans un groupement linéaire, comprenant le procédé selon la revendication 5, et comprenant en outre pour chaque module,
- la mise en place de la première surface (80) de butée du module en contact avec la seconde surface (90) de butée d'un module adjacent.
10. Procédé de fabrication d'une tête d'impression pour un appareil d'impression à jet d'encre, comprenant le procédé selon l'une quelconque des revendications 7 à 9, dans lequel les modules comprennent des dispositifs d'impression à jet d'encre.
